

PMSM FOC of Industrial Drives using the 56F84789

by: Pavel Rech

1 Introduction

This application note deals with the field-oriented control (FOC) of a permanent magnet synchronous motor (PMSM) with the DSC 56F84789. The incremental encoder is used for position and speed feedback in this application. This is the typical control algorithm used in industrial drives. The application is controlled by the powerful Freescale Digital Signal Controller (DSC) 56F84789 dedicated to advanced motor control applications. The DSC 56F84789 offers a rich and advanced peripheral set which includes programmable timers, an eFlexPWM module, analogue and communication modules, and so on. This application note describes the control algorithm, software design and hardware set-up using the Tower kit.

Figure 1. The real application

2 Application Features

- Executing a field-oriented control algorithm for a PMSM
- Encoder on the shaft to sense the rotor position and speed
- Controlled by the DSC 56F84789
- Both directions of rotation and two closed-loops implemented:
 - Speed closed-loop with a PI Controller
 - Current closed-loop with two PI Controllers
- Speed range: 0 – 3000 rpm (field weakening is not implemented)
- H/W used:
 - TWR-MC-LV3PH - Low-Voltage 3-Phase Motor Control Module
 - TWR-56F8400 - MC56F84789 Motor and Power Control MCU Module
- User interface:
 - Using buttons on the Tower MCU board
 - Using a graphical interface in FreeMASTER
- Autonomous mode – changing the required speed automatically
- Tuning Wizard supported – easy setting of the control structure parameters

3 DSC 56F844x/5x/7x Key Features

Each device in the 56F844x/5x/7x family, based on the 32-bit 56800EX core, combines, on a single chip, the processing power of a 32-bit DSP and the functionality of a microcontroller with a flexible set of peripherals. The 56F844x/5x/7x family can be characterized by the following:

- cost-effectiveness
- configuration flexibility
- compact program code

This device is suitable for many motor control or power conversion applications. The DSC 56F844x/5x/7x family has a modernized 56800EX core, which is based on a dual Harvard-style architecture consisting of three execution units operating in parallel, allowing as many as six operations per instruction cycle. The optimized instruction set allows straightforward generation of efficient, compact DSP and control code. The instruction set is also highly efficient for C compilers to enable rapid development of optimized control applications. The DSC from the 56F844x/5x/7x family supports up to 100 MHz

program execution from both internal flash memory and RAM. Both on-chip flash memory and RAM can also be mapped into both program and data memory spaces. Two data operands can be accessed from the on-chip data RAM per instruction cycle.

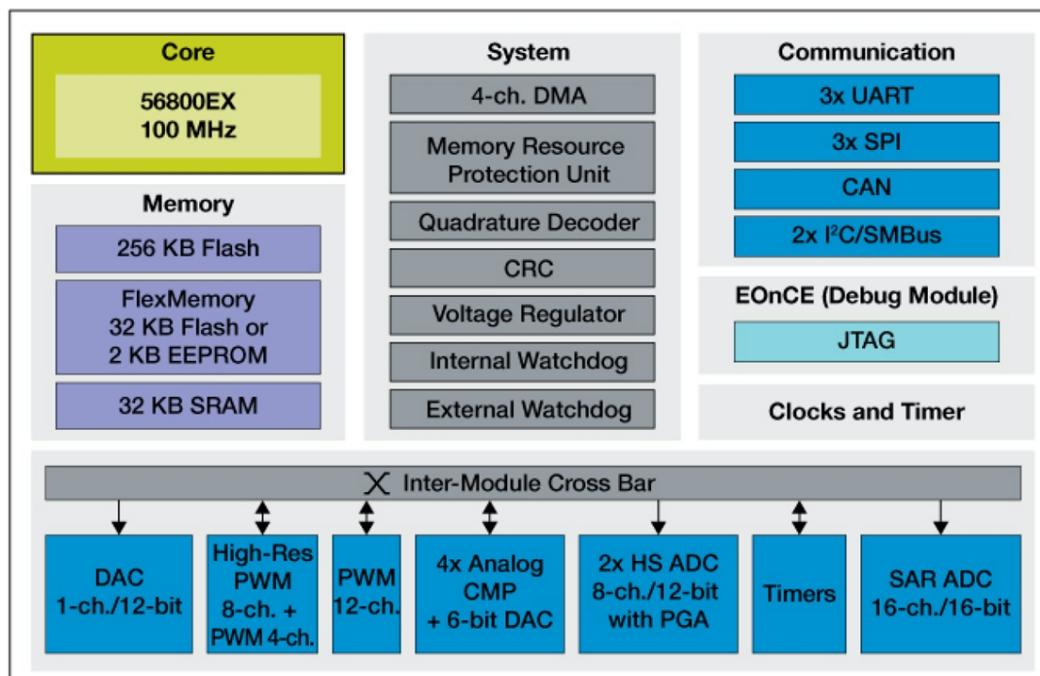

Figure 2. MC56F84xx Block Diagram

4 PMSM Control Principle

The FOC, or in other words the vector control, is one of the most widely used control methods not only for PMSM. The aim of field-oriented control is to separate the current loop by the system of coordinates on two components, and, by using them, control the motor torque and field excitation (magnetic flux) independently. If speed control is required, at least three controllers are necessary. The controllers are placed in various speed control loops depending on the time constants of the controlled quantities. Accordingly, there are two control loops implemented:

- slow control loop – provides the speed regulation and compensates the mechanical time constant of the machine. The loop calculates the deviation between the required speed and the real rotor speed obtained from the rotor position time change. The PI controller processes the deviation and creates the required torque current component. This routine is called regularly, for example, by the PIT. The slow control loop is executed in 1ms.
- fast control loop – regulates motor currents and compensates the electrical time constant of the stator circuit. This loop develops the motor torque and can also generate the field excitation in the case of optional field weakening. The current control loop ensures the following operations:
 - Using the Clark and Park Transformations, the two current components in rotating coordinates are transformed from the 3-phase sensed currents.
 - The direct-axis current component influences the field excitation of the machine, but owing to the permanent magnet, this component is kept at a zero value.

PMSM Control Principle

- The quadrature-axis current component is proportional to the machine torque on conditions, such as constant the field excitation and keeping the electrical angle between the stator and the rotor flux at 90° . The Space Vector Modulation (SVM) generates three components of the phase voltages for the PWM module. This routine is called by ADC conversation complete interrupt. The fast control loop is typically executed in $62.5 \mu\text{s}$ (for a 16 kHz PWM frequency).
- The current control loop is executed immediately when new values of currents are ready in the ADC result registers. The speed control loop has a lower priority and is executed as soon as the PIT overflow occurs. The ADC with PWM module synchronization through the crossbar ensures that two phase currents are sensed in the right time instance when the current flows in an applicable shunt resistor.

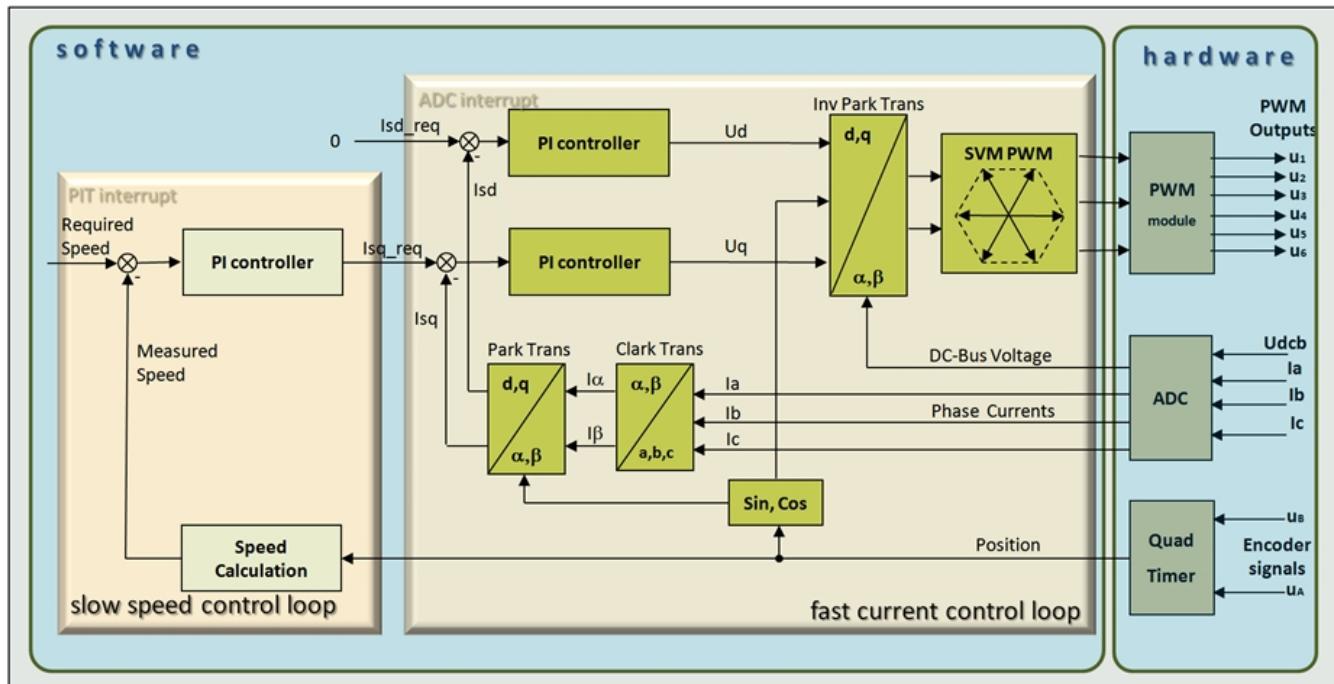

Figure 3. PMSM Field-oriented Control Principle

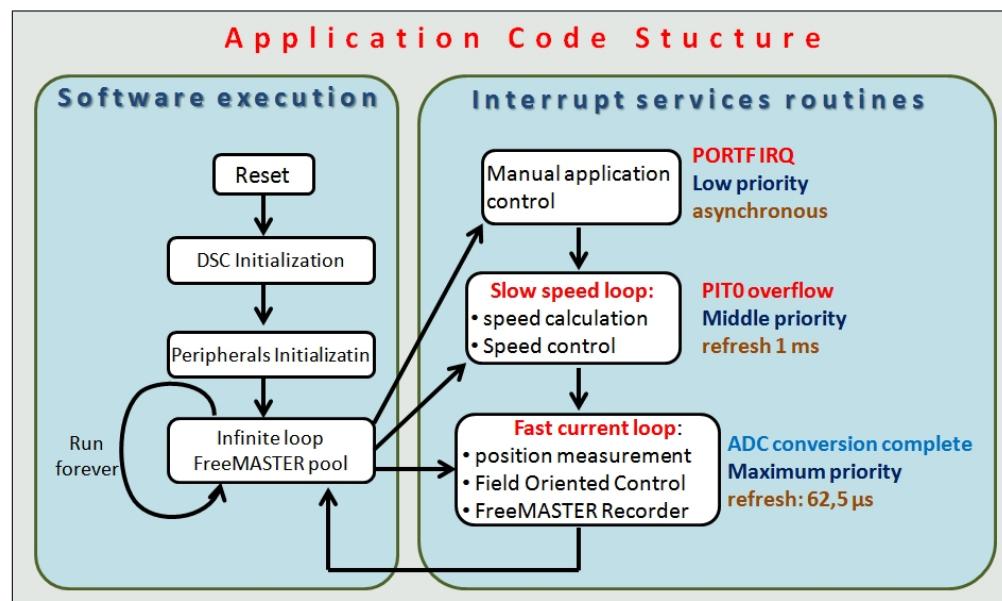

Figure 4. Application Code Structure

The incremental encoder is used as the position and speed sensor. It generates the A, B and Index signals processed by the Quad Timer in Quadrature count mode, which counts the actual rotor position. The encoder signals are processed in two ways. On the one hand, the pulses are counted during the constant period – convenient for higher speeds. On the other hand, the measuring time interval between encoder pulses is measured – convenient for low speeds. This speed processing method increases the precision of the speed measurement at the expense of the second quad timer module with capture functionality needed.

5 Application Operation

The Application can be operated using two buttons, SW1 and SW2, or by using the FreeMASTER graphical control interface. The SW2 button first starts the control algorithm and then increases the speed. The SW1 button decreases the speed, turns off the application, clears a flag or turns the application to the autonomous mode.

6 System Concept

The application is based on Freescale's modular development platform - the Tower system. Apart from the Tower system, this application includes the 3-Phase permanent magnet synchronous motor. There are two boards only in the Tower system:

- TWR-MC-LV3PH – Low-Voltage 3-Phase Motor Control Module
- TWR-56F8400 - MC56F84789 Motor and Power Control MCU Module

These two boards are connected using the primary elevator module, the secondary elevator only keeps the Tower system together. The DSC board with the 56F84789 is placed in the top position of the Tower to enable control of the application using the buttons.

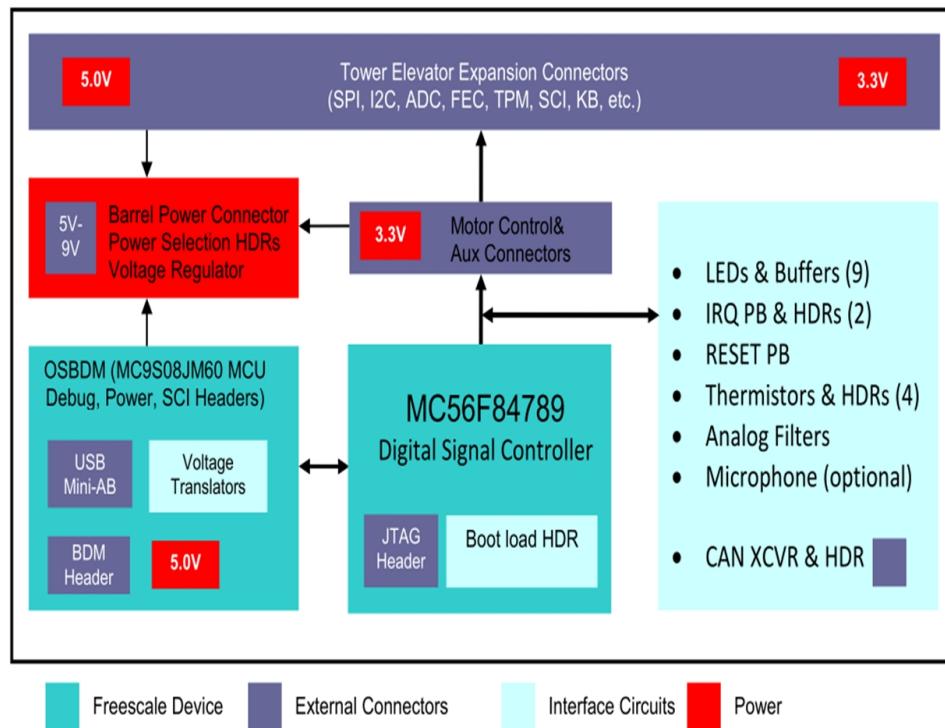

The Figure 2 shows the peripheral set of the MC56F84xx family. For the motor control applications, 6 channels of the PWM module are necessary and 2 fast ADC modules with at least 5 channels. Synchronization of the PWM and the ADC module is an important feature. The MC56F84xx family has a CrossBar module which can easily provide synchronization. The Quadrature decoder is required to decode the Incremental encoder sensor signals. For some applications, can be the communication modules can be required. This application based on the Tower system requires the SPI module for MOSFET driver configuration. Similarly, the SCI communication interface is needed to control the application using the FreeMASTER. The other peripherals are optional.

7 Tower DSC 56F84789 board

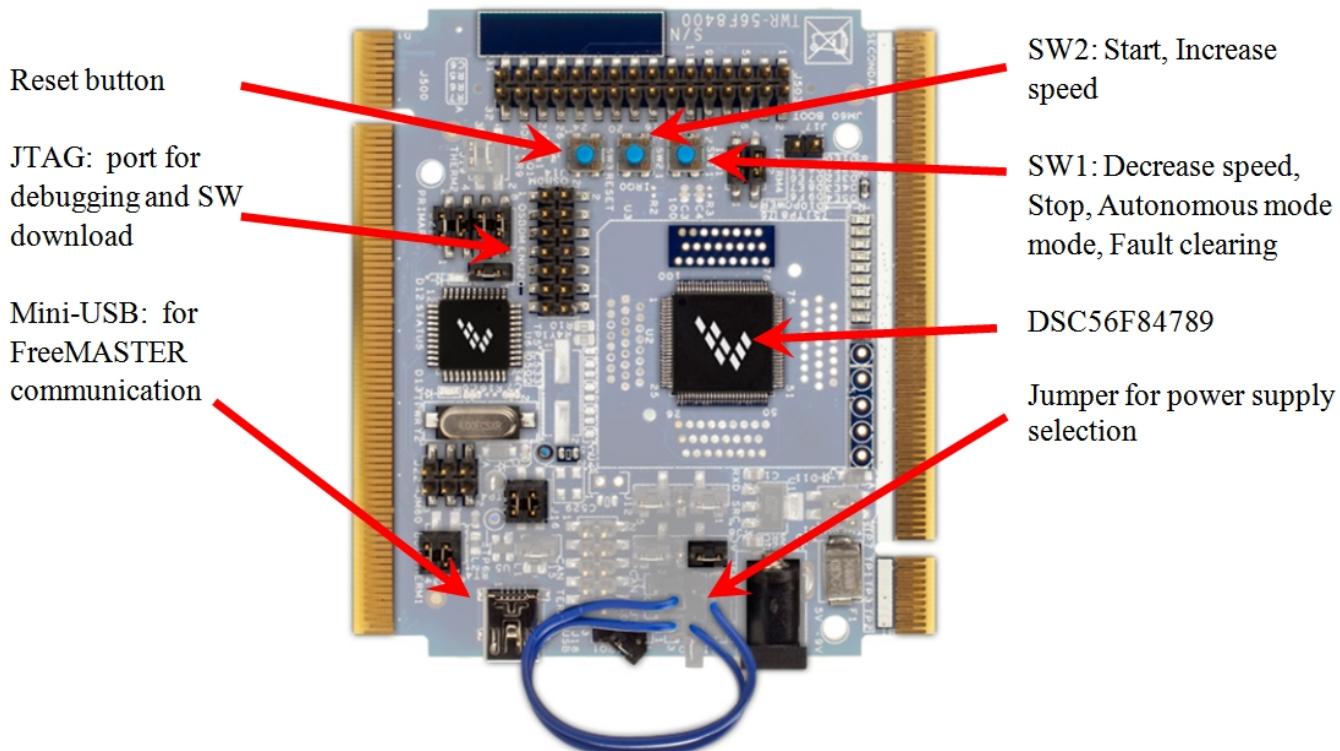

The Figure 5 denotes the Tower DSC board conception. There are three ways to supply power to the Tower DSC board

- through the main power supply connector on the board, from 5 V to 9 V
- through the mini-usb connector, with 5 V
- through the elevator module with voltage generated by the low-voltage tower board

This application uses the third possibility because the Low-Voltage 3-Phase Motor Control Module has to be supplied by 24 V, therefore this voltage is also used for the DSC tower boards.

**Figure 5. TWR MC56F84xx Block Diagram**

The following Figure 6 shows the real DSC board with components, buttons and their programmed functions. There are three buttons, the first one for an application reset and the next two buttons for controlling the application. Using these two buttons, the application can be set to run or stop, change the motor speed, clear the fault or switch to autonomous mode.

**Figure 6. TWR MC56F8400**

The motor is supplied by the Low-Voltage 3-Phase Motor Control Module offered by Freescale, which is determined for low-voltage motor control applications. The 3-Phase module does not only generate voltage pulses for supplying the stator, but this board can also process signals from the incremental encoder or Hall sensor and, of course, ensures the measurement of the phase currents, BEMF voltage, DC-bus current and voltage.

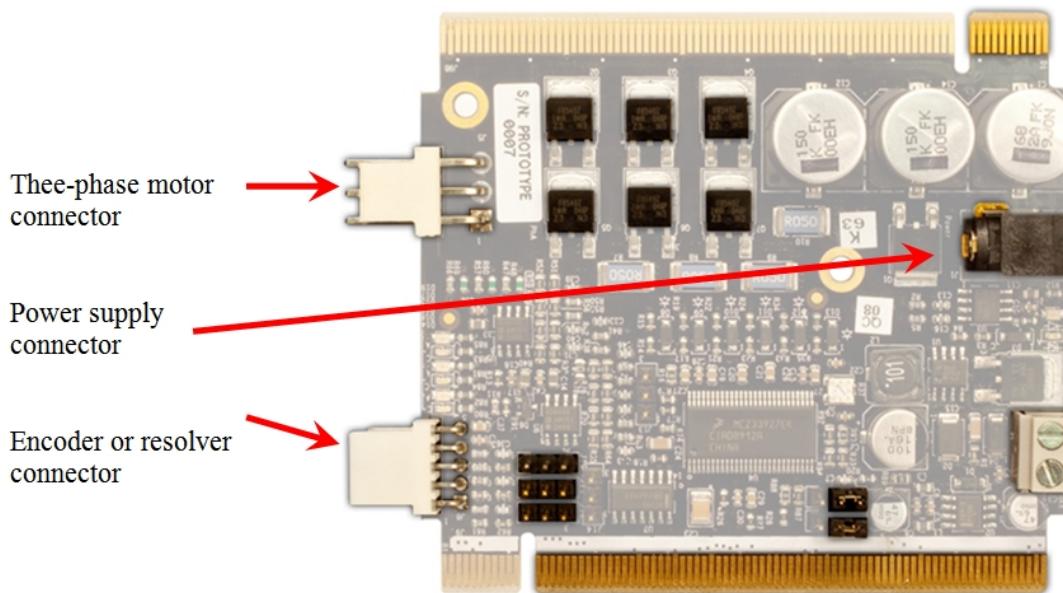

Figure 7. Low-Voltage, 3-Phase Motor Control Tower System Module

8 Peripherals for PMSM control

From the DSC peripheral perspective, the vector control of the PMSM requires a 6-channel PWM block for 3-phase sine wave generation, a time base for the speed control loop, and the ADCs synchronized with the PWM module for the current sensing. In the case of the encoder feedback, a timer with a quadrature decoding capability is required. The following table shows the list of peripherals used in the application.

Group	Module	Sub-module and Channels available	Used in the Application	Purpose
Timers	PIT	2 channels	2 channel	speed loop time bases and autonomous mode time base
	PWM	PWMA - 4 sub-modules	3 sub-modules	generation of 6 PWM channels for the PMSM
		PWMB - 4 sub-modules	-	
	PDB	1 module	-	
	Quad timer	TMRA- 4 sub-modules	2 sub-modules	Quadrature encoder processing
		TMRB-4 sub-modules	-	
Analogue	ADC	ADC12 - 8 channels	3 channels	2 channels for PMSM phase currents and 1 for DC-bus PMSM voltage measurement
		ADC12 - 8 channels	2 channels	2 channels for PMSM phase currents
		ADC16 - 24 channels	-	
	CMP	4 channels	-	
	DAC	2 channels	-	
Other	crossbar	XBARA - 32 selections	2 selections	Driver fault for PWM, ADC – PWM synchronization
	crossbar	XBARA - 8 selections	-	
Communication	QSCI	3 sub-modules	1 sub-modules	For FreeMASTER communication
	QSPI	3 sub-modules	1 sub-modules	For MOSFET Driver communication
	I2C	2 modules	-	
	FlexCAN	1 module	-	

Figure 8. The 56F84789 peripherals overview for PMSM FOC

The right peripheral interconnections are also necessary to execute the FOC. Figure 9 denotes the interaction among the control algorithm, peripheral and hardware. It is essential that PWM – ADC synchronization is realized through the crossbar switch.

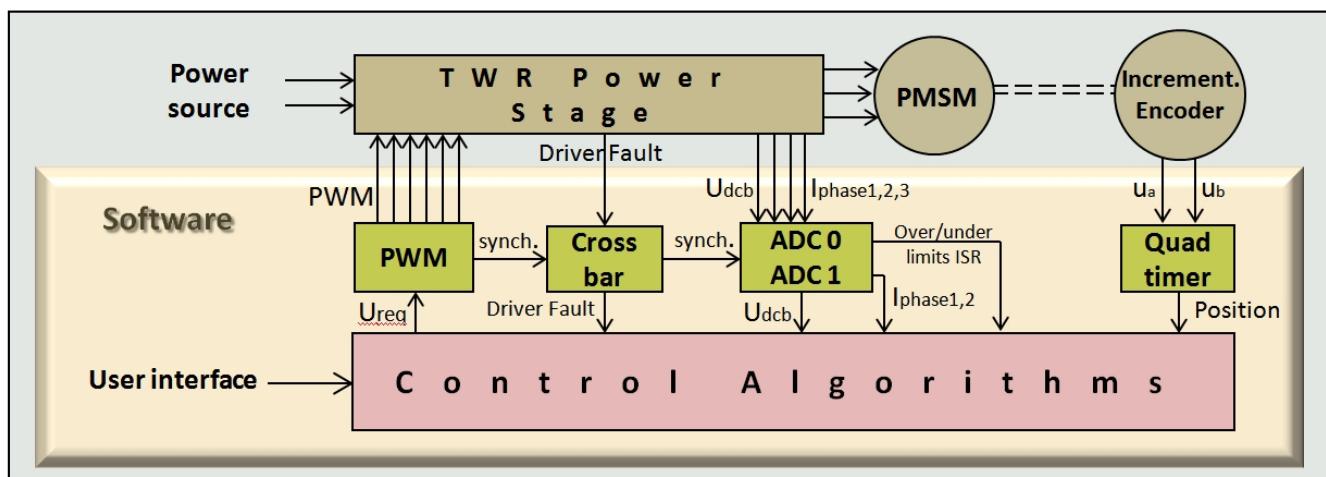

Figure 9. Peripheral Interconnection

9 Faults Protection

The control algorithm includes protection against these faults:

- S/W phase overcurrent based on ADC low/high limits automatic comparison.
- S/W DC-bus overvoltage based on ADC high limit automatic comparison.
- H/W DC-bus overcurrent based on driver functionality connected with the PWM module.
- S/W over/under speed checked by control algorithm speed measurement.

The DC-bus overcurrent is set to a higher value than the S/W phase overcurrent, which is set to a higher value than the current regulator limits. If a HW DC-bus overcurrent fault occurs, the driver will automatically turn off all MOSFETs even though the PWM module would generate the pulses. All faults are indicated by LED on the DSC tower board and by LED on 3-phase low-voltage module concurrently. The FreeMASTER directly indicates which faults occurred.

10 State Machine

The application software is based on the application state machine built on 4 basic states and expanded using 4 run sub-states:

- Initialization - initialize the variables and MOSFET driver.
- Stop - control algorithm runs and the PWM module is disabled.
- Run - control algorithm runs and the PWM module is enabled.
 - Calibration
 - Ready
 - Alignment
 - Rotation
 - Automatic mode
- Fault - control algorithm runs, the PWM module is disabled and the fault is indicated.

The application has to be in one of the basic states at anytime. The switching between states is ensured by short transition functions. The transition between the states can be done automatically (for example, from Init to Stop, or Run to Fault states), or called by the user through variables changing (for example, from Run to Stop state, or Rotation to Automatic mode sub-state). The state machine also supports a multi-motor solution. Information about, the actual state or sub-state is stored in variables and the transition between two states is possible only under satisfied logic conditions. The state machine structure allows for easy incorporation of customer specific code and provides a transparent structure of code.

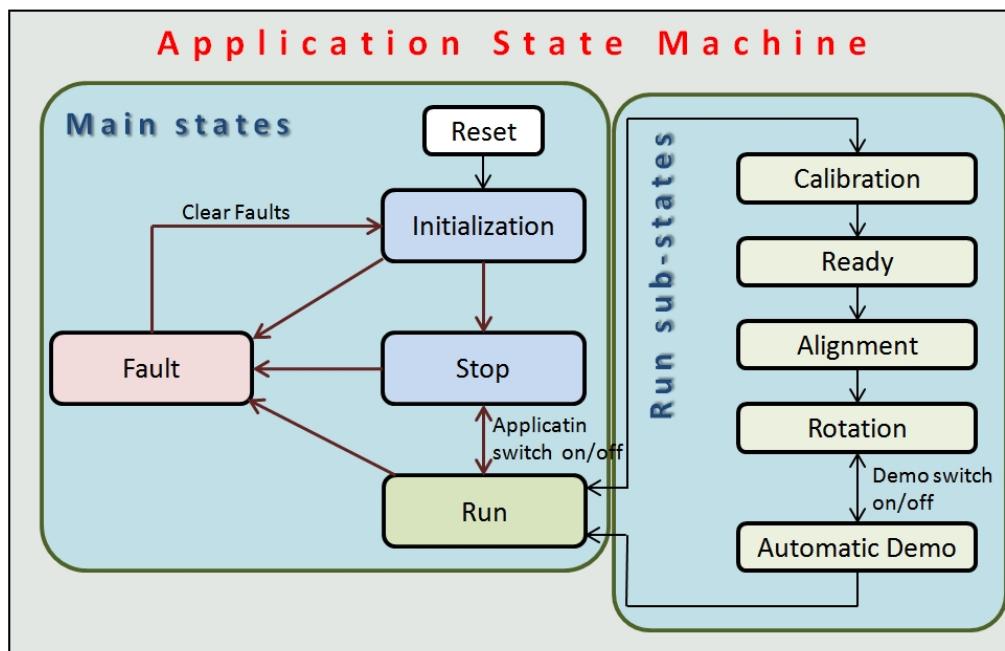

Figure 10. Application State Machine

11 FreeMASTER and Motor Control Application Tuning Tool

The FreeMASTER is a real-time debug monitor and data visualization tool. The graphical interface in FreeMASTER is a more comfortable way to control the application. In this way, the user has more possibilities and feedback over controlling the motor. Moreover, the actual speed values are measured and can be visualized in waveforms.

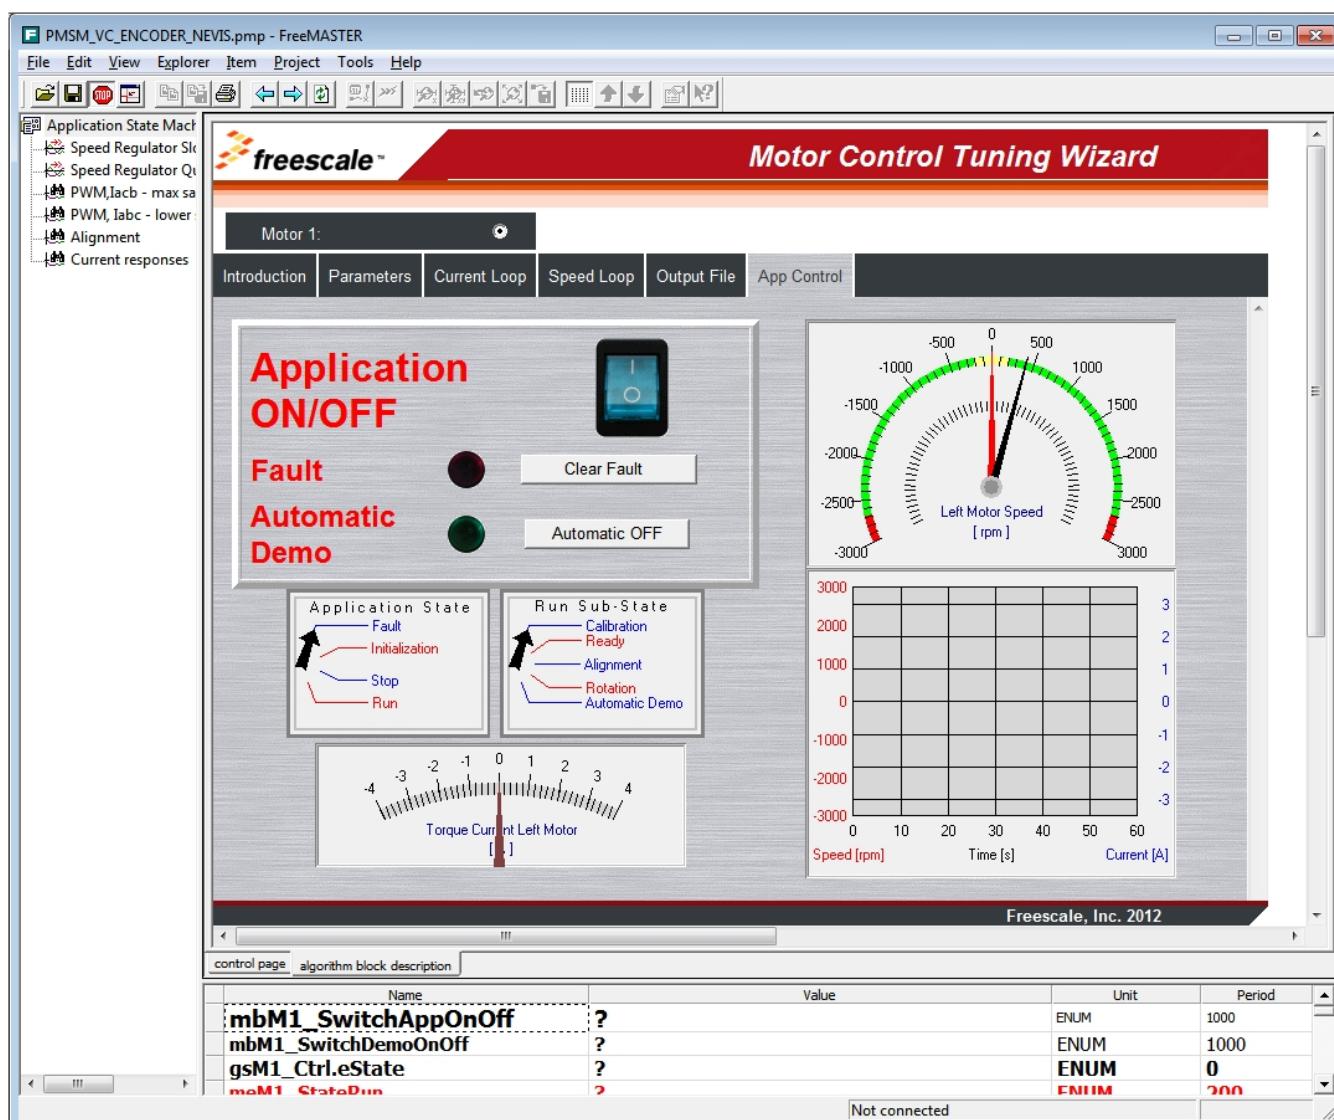

Figure 11. FreeMASTER Graphic Control Interface

The Recorder functionality of the FreeMASTER is excellent for watching what happens in the DSC during motor control processing. The recorder measurement is based on capturing the variables in periodic interrupts. This application uses measurement in the ADC interrupt service routine, meaning each measured sample can be visualized in the recorder. The following Figure 12 shows the example of a transient state of the application triggered by the recorder. This visualization tool supports up to 8 variables – placed according to user selection in up to 6 blocks, the arbitrary variables can be used for triggering.

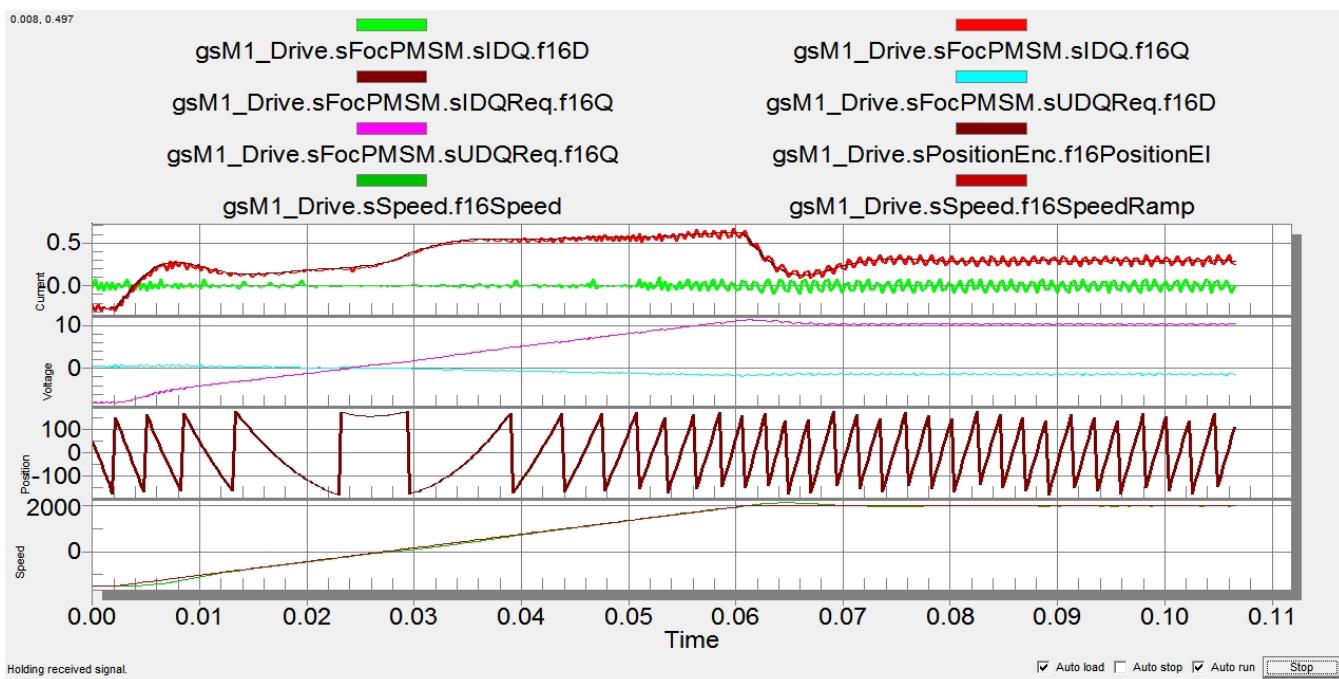

Figure 12. The Response to a Change in Required Speed Captured by the Recorder

The Tuning Wizard is an upper level motor control tool which enables easy parameter configuration of the control loops, motors or observers. Using this tool implemented in FreeMASTER, you can set up and tune the application constants without advanced motor control knowledge. After the drive has been tuned, you can save all constants to the application header file which will be used for project compilation.

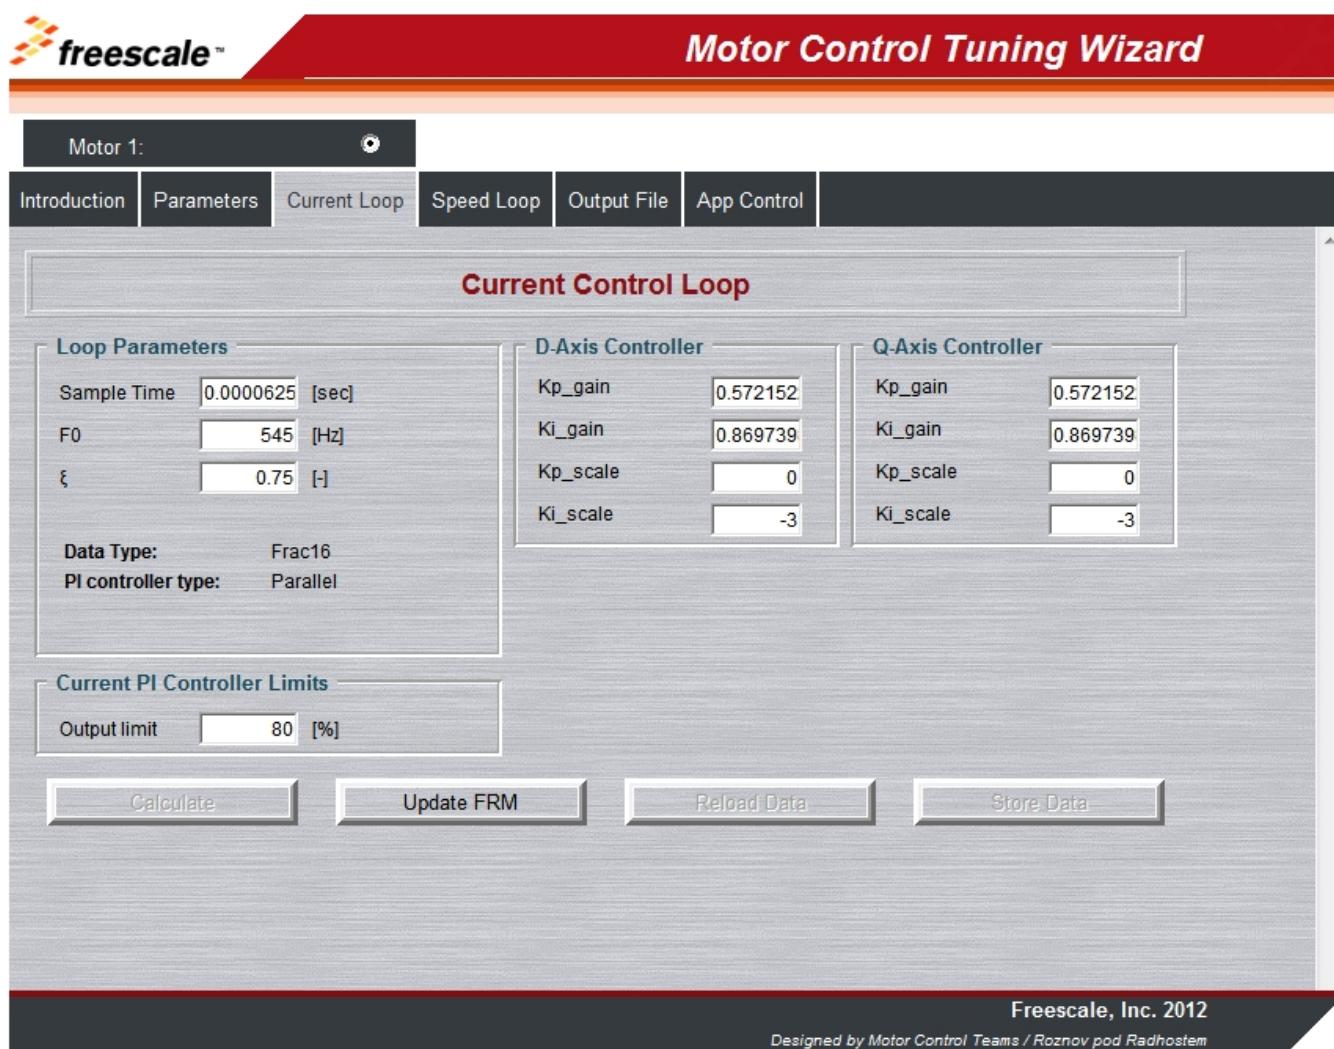

Figure 13. Motor Control Application Tuning Tool

Tuning wizard input parameters can be divided into three groups: Motor parameters, Application scales, Hardware scales. The motor parameters should be found in the motor datasheet. The application and hardware scales depend on the power stage used. The user should write the input application parameters and the parameters of the current and speed loops. The wizard will calculate the other parameters from input parameters after pressing the button Calculate. Then it is possible to write these values of current and speed loops directly into the application variables through FreeMASTER by clicking on button update FRM. The bookmark Output File displays the output header file which is used for writing the application constants directly to the DSC flash memory after compiling the project and downloading the code.
